## How to fix Mass Job cancellation creates DDOS on pbs\_server (around 4.2.x)

**Issue:** How to fix Mass Job cancellation creates DDOS on pbs\_server (around 4.2.x)

**Affected Versions:** 4.2.5, 4.2.x

### Symptom:

In some of the lower to mid versions of Torque cancellations of many jobs either in an array or individual jobs could lead to a sluggish or non-responsive Torque (pbs\_server). Even many jobs reaching walltime limit can trigger this. Also even if you regain control over pbs\_server these cancelling jobs will continue to block resources for the new jobs making resources unusable.

Typical message: Exiting loop because we passed our retry tolerance: 24

### Solution:

The problem is all the moms trying to contact the server at once to cancel their jobs is too much for pbs\_server to handle. Even regular client commands like pbsnodes and qstat may fail. Here are the simple steps I use to regain control.

1 Shutdown the pbs\_server. This maybe easier said than done. In some cases I have had to sig 9 it. - We need it down to restart and regain control.

2 Now restart the server with pbs\_server -c This staggers the server's response to the moms and gives you a few minutes to work on the problem (doing the steps below). Sometimes you may need to repeat this to get enough time to attack the problem

Attacking the problem. Since the jobs were being cancelled anyway you should not feel bad about getting rid of them.

3 Assuming you just started with pbs\_server -c you should now be able to issue commands. Use qstat to look for jobs stuck in 'cancelling'

4 Use qstat -f to see which node or nodes they are on.

5 'Offline' those nodes with pbsnodes -o

6 Restart those moms with pbsnodes -P to purge the junk jobs from those moms. In severe cases you may need to go to the job and array folders and remove any .jb, .ar or .sc files.

7 Slowly, preferably one by one bring the nodes back on line with pbsnodes -c to "clear" the offline status. You should see the culprit jobs clear off the pbs\_server (Torque) and Moab and new jobs should then freely start on those nodes.

# Torque

In most cases this is all that is needed. In some of the more serious cases I have had to follow up in Moab removing the individual jobs from the .ck file as it is not recommended by developers that the .ck file be removed.
